ever, this adjustable feature was omitted, since it was preferable to locate any bias appearing, and to correct it at its source rather than to introduce compensating bias at the repeater.

These developments brought the various d-c telegraph systems into line with the most modern standards, and made them suitable for the high-speed transmission required for the newer teletypewriter equipment. By the late 1920's, however, carrier systems began to assume the leading position in the telegraph field, and all the more recent larger developments have been associated with them. These will be discussed in a forthcoming article.

THE AUTHOR: B. P. HAMILTON was graduated by Columbia University in 1913 with the E.E. degree. He taught there for two years and then joined the Engineering Department of the American Telephone and Telegraph Company in 1915 to work on equipment design and later on field tests of high-frequency and voice-frequency carrier telegraph systems. Mr. Hamilton's work has also involved development problems in connection with the Key West-Havana submarine cable and transcontinental carrier telegraph systems. Since 1930 he has been engaged in developing voice-frequency carrier telegraph systems and applications to carrier telephone channels.
